TITLE: A device for preventing explosion of vessels containing flammable liquids.  
Class 81, No. 84930

SOURCE: Izobreteniya, promyshlennyye obraztsy, tovarnyye znaki, no. 2, 1967, 189

TOPIC TAGS: flammability, fire protection

ABSTRACT: This Author's Certificate introduces a device for preventing explosion of vessels containing flammable liquids by inserting a double corrugated tube in the neck of the vessel to create a flame extinguishing labyrinth. To provide for the proper pouring capacity and make it possible to empty the vessel completely, the ribs of the inner tube are located in the gaps between those of the outer tube. The ribbing in the tubes is produced by folds in the material from which the tube is made through flattening of these folds.

Title : Raising Cabbage by Means of Seed Planting.

Orig Pub: S.kh.Sibiri, 1957, No 4, 51-54.

Abstract: A non-seedling method of raising cabbage was used at the "Put' Il'icha" Kolkhoz, Omskaya Oblast. In 1956, cabbage harvest on an area of 49.5 ha comprised 182 c/ha. With this non-seedling method, cabbage is less susceptible to disease and has a higher percentage of dry matter and sugar; in the early development phases good "hardening" occurs, as well as resistance to drought, sukhoveys, [dry winds] and May frosts. Detailed agricultural engineering is cited. The best predecessor is fallow

Abstract: plowed without a blade grader. Planting is done with vernalized seeds. It is indicated that the basic reason for failure of the non-seedling method of raising cabbage is insufficient pest control.

TITLE: Antigenicity of DNA bacteriophages

SOURCE: Byulleten' eksperimental'noy biologii i meditsiny, v. 62,  
no. 10, 1966, 75-78

TOPIC TAGS: antigen , DNA, bacteriophage, ~~bacteriophage~~,  
medical experiment

ABSTRACT: The antigenic properties of DNA bacteriophages have been  
debated in the literature. To determine whether or not DNA phages  
possess antigenic properties, DNA preparations from T2 phages consisting  
mostly of phage protein were used as the antigenic component in the  
diffusion precipitation in agar and complement-fixation reactions.  
Only partially "deproteinized" DNA protein (denatured by phenol) yielded

TITLE: The mineralogy of contact rocks of the Lovozero mountain range

SOURCE: Akademiya nauk SSSR. Institut mineralogii, geokhimii i kristallo-khimii redkikh elementov. Trudy, no. 9, 1962. Redkiye elementy v massivakh shchelochnykh porod. 3 - 35

TEXT: In continuation of earlier papers the authors report on mineralogical investigations of rocks of the Lovozero mountain range generated in contact with gneisses. These rocks border in a plane band the whole Lovozero range forming a complex contact zone of 50 to 300 m width. In 1960 the present authors determined the composition of this zone of at least two genetically different complexes of rocks. The present paper contains the results of investigations by I.P. Tikhonenkov in 1957 - 1958 and R.P. Tikhonenkova in 1958 - 1960. Mineralogical geological data and data on the chemical composition of the following typomorphic and accessory rare earth minerals of the contact rocks of Lovozero range are presented: Haloides - fluorite; oxides - loparite, pyrochlore,

Card 1/4

ilmenite, anatase, quartz; carbonates - magnesite, bastnaesite, mineral no. 1; silicates - pectolite, apophyllite, epididymite, lithium micas, biotite, stilpnomelane, hisingerite, endialyte, zircon, catapleite, elpidite, wehelerite, vlasovite, sphene, aenigmatite, narsarsukite, ramsayite, astrophyllite, lamprophyllite, neptunite, nnadkevichite, labuncovite, rinkolite, orthite, mineral no. 2; and phosphates - apatite and rhabdophanite. The chemical analyses were carried out in different laboratories and by different analysts. The following conclusions are drawn by the authors at the end of the present report: The data presented demonstrate that different minerals are confined to certain types of rocks. Among these there can be clearly distinguished two paragenetic associations corresponding to two genetically different complexes of rocks - fenites and postmagmatic syenites. The main part of rock-forming and accessory minerals of nepheline syenites of the range are in the fenites. Besides the usually contained minerals, nepheline syenites of the endocontact facies of this complex contain the characteristic minerals murmanite, aenigmatite, astrophyllite, and neptunite. Narsarsukite is found only in fenites. The following paragenetic association of minerals is characteristic of rocks formed in different stages of the postmagmatic syenitization process: zircon, pyrochlore, vlasovite, weheler-

ite, ilmenite, anatase, catapleite, elpidite, radiate sphene, biotite, stilpnomelane, orthite, carbonates, quartz, fluorite, apatite, and also accessory lithium micas, fluorocarbonates of rare earths, etc. Some minerals like ilmenite, ramsayite, and sphene might be present in different groups of rocks, but some of them (ramsayite, sphene) show in each case characteristic forms of formation. This might characterize rocks from one complex in comparison to another in consideration of other factors. Ilmenite must be considered as a characteristic contact mineral occurring in nepheline syenites as a result of the interaction between the alkaline magma and the enclosed rocks. The present paper contains only results on contact rocks formed in consequence of an interaction between alkaline solutions and old archean gneiss series. Data on the mineralogy of rocks emerging after processing of sedimentary-effusive formations, which are found in the form of xenolithes, are not presented since these investigations are not finished yet; however, first results indicate that these formations are also intensively mineralized. There are also present two complexes of contact formations - one is connected with a magmatic replacement, the other with the influence of postmagmatic solutions. Among other widely distributed minerals in this mountain range were found in the formation mentioned last, the following

TITLE: Regularities in the distribution of rare elements in contact rocks of the Lovozero mountain range

SOURCE: Akademiya nauk SSSR. Institut mineralogii, geokhimii i kristallogimii redkikh elementov. Trudy, no. 9, 1962. Redkiye elementy v massivakh shchelochnykh porod. 125 - 141

TEXT: The singularity of structure and composition of the contact-metasomatic rocks of the Lovozero mountain range were discussed by the authors in earlier papers. In the present work preliminary results are presented of investigations on the distribution of the rare elements lithium, rubidium, beryllium, gallium, and the rare earths zirconium and niobium. Mean samples of all types of contact-metasomatic rocks were taken in a weight of 10 kg, and after grinding 0.5 kg batches were used for chemical analyses. All chemical and spectral analyses were carried out in the laboratories of the IMGRE. The lithium, rubidium, and potassium determinations were carried out through flame photometry by the

Regularities in the distribution of rare elements .... A057/A126

analysts T.G. Uvarova and G.N. Popova. The beryllium content was determined through the quantitative spectral method by N.M. Bronina, while the rare earths niobium, zirconium, and gallium were determined chemically by the analysts Z. Katayeva, N. Korotkova, M. Kukharchik, O.F. Sazonova, A. Manukhova, Z. Eurova, A.M. Kislov, T.A. Kapitanova. The X-ray spectral analyses of rare earth minerals were done by R.L. Barinskiy. The authors give in separate chapters for each of the analyzed elements corresponding mineralogical, structural, and geochemical information, and data on the composition of rocks. Some data refer to deposits in the Vavnbed Mountain. The authors conclude: The investigated contact formations are enriched by the mentioned rare elements, since their mean content is higher than the mean content in the main complexes of rocks of the range. The distribution of the rare elements shows in the contact zone certain regularities corresponding to singularities of metasomatic processes at the different stages of the formation of the Lovozero range. Thus occurs the formation of contact rocks in the process of fenitization with a considerable addition of the following rare elements from the magma: beryllium, niobium, zirconium, rare earths, etc. The main part of rare elements disperses in the structures of different ferite minerals, while part of them form complicated complex compounds.

Regularities in the distribution of rare elements .... A057/A126

A precisely developed tendency to a separation of the main part of rare elements and their concentrated isolation in form of proper minerals occurs during the postmagmatic syenitization. It can be seen an evacuation of rare elements from the replacing rocks (fenites, nepheline syenites, gneisses). In dependence of the stage of postmagmatic syenitization, the interaction of solutions with the enclosing rocks, and the change of their acidity-alkalinity there occurs a redistribution of rare elements and a secondary enrichment of separate zones of postmagmatic syenites. Characteristic is the relative enrichment of the rocks of the front zones of the process of postmagmatic syenitization with the most basic components of the group of rare elements in respect to more acidic rocks of the central zones. Lithium and rubidium accumulate generally in the outer parts of bodies in the stages of micatization and especially microclinization. The main mass of niobium minerals forms in the stage of albitization. Here a relative accumulation of gallium happens. This rather precise distribution of rare elements during the stages of postmagmatic syenitization will possibly aid in prospecting and exploring deposits formed by the development of this original metasomatic process. There are 2 figures and 13 tables.

TOPIC TAGS: differential equation, mechanics 13, 44, 55

ABSTRACT: The author considers the system

$$\frac{dx_s}{dt} = \sum_{k=1} p_{sk} x_k + \sum_{\substack{m_1 + \dots + m_s = m \\ m=2, 3}} p_{sm}^{(m_1, \dots, m_s)} x_1^{m_1} \dots x_s^{m_s} \quad (1)$$

(s=1, 2, 3, 4).

After some simplifying assumptions which enable the lowering of the order of the system, he integrates the simplified system of differential equations. Orig. art. has: 32 formulas.

mechanical property, metal aging / AL8 Al-Mg alloy

ABSTRACT: AL8 Al-Mg alloy, one of the toughest alloys of its kind, has the disadvantage of aging in the course of prolonged storage and thus losing some of its ultimate strength and, particularly, relative elongation, and so gradually growing brittle. Apparently it then also loses some of its corrosion resistance. Proceeding from the premise that inoculation with small amounts of certain elements may contribute to the prevention of the decomposition of the solid solution and the retention of sufficiently high mechanical properties, and that in the Al-Mg system the degree of supersaturation of the solid solution is the higher the higher the Mg content of the

alloy, the authors investigated the behavior of this alloy with various proportions of Mg and inoculants when aged. The methods of inoculation and amounts inoculated are described in an article contained in the same issue of Trudy [pp 94-105]. AL8 alloys with and without inoculation with Zr, Ta or Mo were compared after natural aging for 150 days. On this basis it is established that the inoculated specimens, particularly those inoculated with a combination of Zr and Ta or Zr and Mo, display a higher ultimate strength reaching 46 kg/mm<sup>2</sup> after 150 days of aging. Relative elongation somewhat decreases. Particles of second-phase segregations, both those coherently connected with the solid solution and those lacking coherence, can be observed in the structure. A similar pattern is observed on artificial aging ( $t = 75^\circ\text{C}$ , for 100 hr) for the inoculated specimens. The change in the lattice parameter of the solid solution in the AL8 alloy indicates that the inoculants (Zr, Ta, Mo) retard the decomposition of the solid solution by, apparently, blocking the grain boundaries. Compared with the specimens containing 10.5 and 11.5% Mg, the specimens containing 9.5% Mg display the most stable retention of mechanical properties during natural aging.
